Nomadic Communications Labs

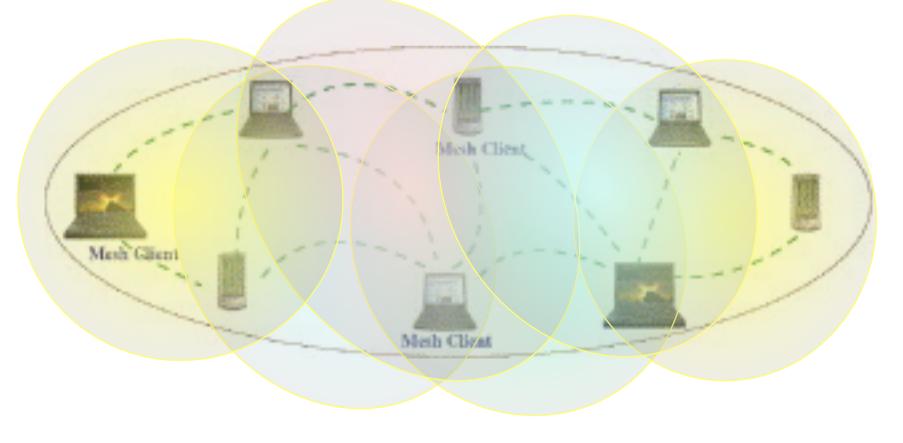

Alessandro Villani avillani@science.unitn.it

Ad-Hoc And Wireless Mesh Network

- Wireless mesh networks bring greater flexibility, increased reliability, and improved performance over conventional wireless LANs
- The main characteristic of wireless mesh networking is the communication between nodes over multiple wireless hops on a meshed network graph

A Mesh – Ad-hoc network

Ad-Hoc can be meshed non single broadcast channel multi-hop require routing

- Efficient routing protocols provide paths through the wireless mesh and react to dynamic changes in the topology, so that mesh nodes can communicate with each other even if they are not in direct wireless range
- Intermediate nodes on the path will forward the packets to the destination

- IEEE created the 802.11s working group to develop a standard for mesh network
- In the meantime there are a lot of network protocol currently available. Some of them are:
 - AODV
 - OLSR
 - B.A.T.M.A.N.
 - BABEL

OLSR is the main candidate to be included in 802.11s standard

- On July 2011 the ballot on the fifth draft of the 802.11s standard was closed with 97.2% of approval
- On September 2011 the 802.11s was approved and published.

Routing Protocol

There are three type of routing protocols:

- Reactive: we search a path between nodes when there is a data to send. No wasting of network bandwidth, best suited for network where the data path change very fast
- Proactive: actively establish and maintain data path both if a data has to be sent or not. Lower latency, but require a higher number of packets to be exchanged
- Hybrid: the protocol use reactive and proactive routing in different situation. The hybrid protocols are more complex to implement.

Routing Protocol

- Lo Cigno will explain the algorithms and how they works
- In our labs we will try to configure a testbed with our laptop and play with the Ad-Hoc wireless mesh network

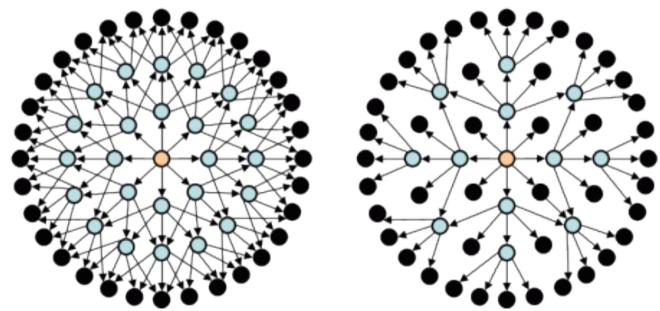

- OLSR: Optimised Link State Routing
- OLSR is a routing protocol for mobile ad-hoc networks
- Information are available at URL:
 - http://www.olsr.org/
- OLSR is defined in the RFC 3626:
 - http://www.ietf.org/rfc/rfc3626.txt

- Proactive, link-state routing protocol
- Based on the notion of Dynamic MultiPoint Relay (MPR)
- Each node N selects from its neighbors an MPR(N) set such that all two-hop neighbors of N are covered by (one-hop neighbors) of MPR(N)
- The idea is to:
 - Reduce flooding overhead
 - Provide optimal flooding distances

As an examples:

- Left image: standard flooding
- Right image: only MPR nodes (light blue) forward the messages

Look at the configuration files: /etc/olsrd.conf

Verify the configuration:

- Change the debug level
- Change the interface name
- Set the IP Version you plan to use (4)

To run OLSRD on our laptop, define a script like the following:

#!/bin/sh

ifconfig eth1 down

iwconfig eth1 mode ad-hoc channel 11 essid
"TEST-OLSR"

ifconfig ethl up

ifconfig eth1 192.168.13.32 netmask

255.255.255.0 broadcast 192.168.13.255

/usr/sbin/olsrd -d 9

Don't forget:

Use different IP addresses on all the client of your ad-hoc network

You should obtain something like:

*** olsr.org - 0.5.6-r4 ***

- BATMAN: Better Approach To Mobile Ad hoc Network
- BATMAN is a routing protocol for multi-hop ad-hoc mesh networks
- Information are available at URL:
 - <u>http://www.open-mesh.net/</u>
- An IETF draft of the protocol is available at URL:
 - <u>http://datatracker.ietf.org/doc/draft-wunderlich-openmesh-manet-routing/</u>

- Proactive routing protocol
- Decentralized knowledge of routing information:
 - No single node has the route to all destinations
 - Each node only maintains the general direction toward the destination and relays the data to the best next-hop neighbor

- To establish the general direction toward a destination:
 - Better link will provide faster and more reliable communication
 - Every node periodically sends out broadcast message (Originator Messages) to advertise its existence

Look at the configuration files: /etc/default/batmand

Verify the configuration:

- Change the debug level
- Change the interface name

To run BATMAN on our laptop, define a script like the following:

#!/bin/sh

ifconfig eth1 down

iwconfig eth1 mode ad-hoc channel 11 essid
"TEST-BATMAN"

ifconfig eth1 up

ifconfig eth1 192.168.13.33 netmask

255.255.255.0 broadcast 192.168.13.255

batmand -d 4 eth1

Don't forget:

Use different IP addresses on all the client of your ad-hoc network

You should obtain something like:

```

- BABEL is proactive routing protocol
- It is based on a loop-free Distance Vector Algorithm
- Information are available at URL:
 - http://www.pps.jussieu.fr/~jch/software/babel/
- An IETF draft of the protocol is available at URL:
 - <u>https://datatracker.ietf.org/doc/draft-chroboczek-babel-routing-protocol/</u>

Babel uses history-sensitive route selection:

- If there are more than one route, the selected one is the already established path
- Babel execute a reactive update and force a request for routing information when it detects a link failure from one of its neighbors

Look at the configuration files: /etc/babeld.conf

Verify the configuration, put something like:

interface eth1 wired false

To run BABEL on our laptop, define a script like the following:

#!/bin/sh

iwconfig eth1 mode ad-hoc channel 11 essid "TEST-BABEL"

ifconfig ethl up

ifconfig ethl 192.168.13.32 netmask

255.255.255.0 broadcast 192.168.13.255

babeld -d 5 eth1

Don't forget:

Use different IP addresses on all the client of your ad-hoc network

You should obtain something like:

```
Adding network eth1.

The Report

- Setup an Ad-Hoc network with 2/3/4/... laptops
- Test at least two of the Multi-Hop routing protocol
- Test the throughput using netperf/iperf and using ping to verify the number of hop
 - Try to setup a testbed with 1, 2, 3, ... hops
 - Verify the bandwidth for all the possible couple of destination (1, 2, 3, ... hops)

Optional:

- Evaluate the ratio between 1 hop and 2/3/... hops throughput obtained in the previous test.
- Run the previous test changing the rate of the wireless card involved into the test
- Evaluate again the ratio between 1 hop and 2/3/ ... hops throughput
- There is any difference?

Optional:

- Run a 2 hops test with just 3 laptops
- Run the same test as before, using 4 laptops (you have two laptops available ad intermediate node)
- There is any difference in the performance? How many times the routes changes during the second test?

Optional:

- In a 2/3 hop scenario stop one of the node involved in the test and verify how long it takes to find the new route
- Optional:
 - Implement the same topology don't using iptables but moving the laptops around the buildng. There is any changes in the throughput?

Two interesting starting points:

- M. Abolhasan, B. Hagelstein, J. C.-P. Wang; <u>Real-world performance of current proactive multi-hop mesh protocols</u>
- D. Murray, M. Dixon and T. Koziniec; <u>An</u> <u>Experimental Comparison of Routing Protocols in</u> <u>Multi Hop Ad Hoc Networks</u>

When you assign an IP address to the wireless interface, Linux insert a default route for the corresponding network:

mylaptop> sudo ifconfig eth3 192.168.10.100
mylaptop> route -n
Kernel IP routing table
Destination Gateway Genmask Flags Metric Ref Use Iface
192.168.10.0 0.0.0.0 255.255.255.0 U 0 0 0 eth3

After the configuration of the wireless, remove this route, to assure the correct behavior of the routing protocols:

mylaptop> sudo route del -net 192.168.10.0 netmask 255.255.255.0

Given 3 nodes: A, B, C

Using OSLR, we want to force A to communicate with C going through B

On laptop A:

iptables -A INPUT -s $x_c.y_c.z_c.w_c$ -p UDP --source-port 698 -j DROP

On laptop C:

iptables -A INPUT -s $x_a.y_a.z_a.w_a$ -p UDP --source-port 698 -j DROP

Other solution:

iptables -A INPUT -m mac --mac-source A^cB^c:C^cD^c:E^cF^c:G^cH^c:I^cL^c:M^cN^C -p UDP -source-port 698 -j DROP iptables -A INPUT -m mac --mac-source A^aB^a:C^aD^a:E^aF^a:G^aH^a:I^aL^a:M^aN^a -p UDP -source-port 698 -j DROP

Given 3 nodes: A, B, C

Using BATMAN, we want to force A to communicate with C going through B

On laptop A:

iptables -A INPUT -s $x_c.y_c.z_c.w_c$ -p UDP --source-port 1966 -j DROP

On laptop C:

iptables -A INPUT -s x_a.y_a.z_a.w_a -p UDP --source-port 1966 -j DROP

Other solution:

iptables -A INPUT -m mac --mac-source A^cB^c:C^cD^c:E^cF^c:G^cH^c:I^cL^c:M^cN^C -p UDP -source-port 1966 -j DROP

iptables -A INPUT -m mac --mac-source A^aB^a:C^aD^a:E^aF^a:G^aH^a:I^aL^a:M^aN^a -p UDP -source-port 1966 -j DROP

To drop/reject packets (so we force the use of a multi-hop path):

iptables -A INPUT -m mac --mac-source A¹A⁰:B¹B⁰:C¹C⁰:D¹D⁰:E¹E⁰:F¹F⁰ -j DROP

□ To accept packets:

iptables -A INPUT -m mac --mac-source A¹A⁰:B¹B⁰:C¹C⁰:D¹D⁰:E¹E⁰:F¹F⁰ -j ACCEPT

• To clear the iptables:

iptables -F
