**Abstract:** In our work a new approach, the Distributed Knowledge Management (DKM) approach, is used and organizations are seen as constellations of communities, which "own" local knowledge and exchange it through meaning negotiation coordination processes. In order to reify communities within a DKM system, the concept of Knowledge Node (KN) is used and then applied in a case study: a complex Italian national firm, the Impresa Pizzarotti & C. S.p.A. All communities of practices are unveiled and reified as KNs within a high level architecture of a DKM system. In this paper it is argued that, even if knowledge has to be organized and made useful to the whole organization, there are types of knowledge that must be managed in an autonomous way, and the DKM approach is a good system which to deal with coordination/negotiation processes.

**Key Words:** Distributed Knowledge Management, Organizational Units, Communities, Knowledge Nodes, Case Study

## 1 Introduction

Most KM systems aim at creating large, homogeneous knowledge repositories, in which corporate knowledge is made explicit, unified, represented and organized according to a unique – supposedly shared – conceptual schema (e.g. an ontology, a classification system) [Davenport et al., 1998], [Borghoff and Pareschi, 1998].

In this work it used the DKM approach [Bonifacio et al., 2002d] in which it is argued that traditional KM systems, and in particular the unique and objective conceptualization of corporate knowledge, are incompatible with the very nature of knowledge, and consequently are often deserted by users. The DKM approach is based on two main principles: the principle of autonomy, which grants organizational units a high degree of semantic autonomy in managing their local knowledge (perspective making [Boland and R.V.Tenkasi, 1995], or single loop learning [Argyris, 1999]), and the principle of coordination, which allows each

organizational unit to exchange knowledge with other units through processes of perspective taking [Boland and R.V.Tenkasi, 1995] or double loop learning [Argyris, 1999]. Therefore, complex knowledge-based organizations can be seen as "constellations" of local "knowledges", that is to say organizational units either formal (e.g. divisions, market sectors) or informal (e.g. interest groups, teams) exhibiting some degree of semantic autonomy, namely the ability to manage knowledge locally and to develop a specialized perspective on the world through social interaction, participation and reification processes [Wenger, 1998].

A KM system, which supports both the principles of autonomy and coordination, and is based on the DKM approach, is called DKM system, which considers local heterogeneity, and negotiation/coordintation of different conceptual schemas [Bouquet et al., 2002], as potential sources of new insights/ideas and innovations which are the basis of organizational learning and adaptability.

## 2   Knowledge Nodes as organizational units

In order to develop a DKM system within a firm, the new concept of Knowledge Node [Bonifacio et al., 2002a] is adopted to reify organizational units (figure 1(a)) considering:
  – the knowledge owner: an individual (e.g. the worker, the manager) or a collective entity (e.g. team, community, division, office) that has the capability of managing its own knowledge;
  – the system of artifacts: procedures, activities, documents, archives, technologies, languages, and so on, used by the knowledge owner to manage local knowledge in a way that best suits its environmental condition and its needs;
  – the context: an explicit representation of a knowledge owner's perspective (or personal conceptual schema).

The DKM system is composed by a "constellation of KNs" (see figure 1(b)), each one managing knowledge in an autonomous way, and exchanging knowledge through negotiation/coordination processes[1].

## 3   The case study: Impresa Pizzarotti & C. S.p.A.

To analyze a complex Italian building industry: Impresa Pizzarotti & C. S.p.A. we made 36 ethnographic interviews with workers of 16 different roles, and we

---

[1] One of the most suitable technological solutions for a DKM system is the creation of a peer to peer system, in which each peer has the characteristics of a KN [Bonifacio et al., 2002e]. This architecture is under development as part of EDAMOK (http://edamok.itc.it/), a joint project carried out by the Institute for Scientific and Technological Research (IRST, Trento) and by the University of Trento (Italy).

**Figure 1:** A DKM system composed by KN

visited 3 building yards. This analysis allowed us to unveil KNs looking at knowledge owners, the systems of artifacts, the contexts and more important the kind of knowledge that is exchanged within a community and the way in which people negotiate/coordinate knowledge across the whole organization.

The organizational model of the firm is complex because the production areas are spread out over the country and in Europe, and the center is composed by service offices which support the production (e.g. the HR office, the quality office, the administration office). Each building yard is managed in an autonomous way, in fact, it must solve specific problems – which are connected with the kind of production, and other environmental factors (e.g. the weather, local costumers and suppliers) – developing a specialized system of artifacts, and managing knowledge in the way that best suits its needs.

Within each organizational unit (e.g. offices in the central building, and building yards), people, through their work, exhibit some degree of semantic autonomy (e.g. by developing their system of artifacts, different working and problems solving practices, using specialized and personalized languages), therefore the Impresa Pizzarotti & C. S.p.A. might be seen as a constellation of communities of practices (CoPs)[2]

In our analysis, we focused the attention on knowledge exchanging processes, often represented by formalized workflows based on shared artifacts, and institutionalized practices within the firm (e.g. software procedures, modules for requests, periodic meetings). From a KM perspective, such a view has historically originated standardized and shared knowledge repositories that should

---

[2] We observed that concepts as quality, security and so on, are perceived – and related processes are developed– in different ways. For example, on one hand, in the "Barilla" building yard, the quality control process is not a daily activity managed by dedicated resources and it has no specific schedules. On the other hand, in the "Fontanellato" building yard, the quality control is one of the most important processes. In particular, every days workers have to control the quality of products and activities and periodically they meet all together to discuss new quality procedures.
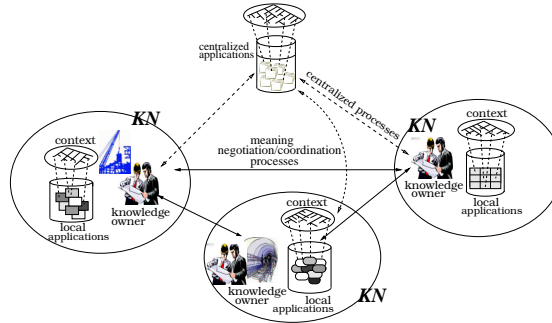

**Figure 2:** DKM system of Impresa Pizzarotti & C. S.p.A.

allow Impresa Pizzarotti & C. S.p.A. to manage a unique version of data, and to coordinate all the organizational processes, developing a set of common and supposedly shared conceptual schemas. These schemas include, for example, shared taxonomies to classify suppliers, project documentation or quality procedures developed and managed by the Electronic Data Processes (EDP) office[3].

We discovered that the centralized KM system has been developed according to the need, expressed by the management, to coordinate each organizational unit creating a common and shared knowledge system, and developing standardized knowledge exchanging processes. Such approach, that was reified in the design of collaborative repositories and workflow applications, revealed some weaknesses which are basically rooted into the distributed nature of knowledge introduced above. As observed during an interview with a manager, if in a building yard a new type of stone-mason's hammer is needed, workers have to draw up a buying request form, then send it (through a document management system, which will store all the information into the enterprize knowledge repository) to the purchasing office which will provide the requested tool. The buying request process is a centralized workflow, developed to deal with the centralized repository and to coordinate all the buying processes of the whole organization. From a KM point of view we can say that the buying request successfully reflected a unique conceptualization schema according to which knowledge is stored and organized within the enterprize knowledge repository.

In our analysis we discovered that quite often the buying request process, although technically correct, is not enough to obtain a good result. In particular, every time the tool requires specific characteristics, the requester and

---

[3] During an interview, the responsible of EDP office said that his work consists in controlling data and information workflows developed within the organization. Workers ask to develop personalized systems which support some specific processes, but the management and the EDP office are worried about the coherence and the transparency of information. For this reason centralized procedure are developed and used across the whole organization but offices and building yards are still asking to use specialized procedures which suit local needs . . .

the company buyer need to exchange additional contextual information using informal communication channels which are not officially considered in the collaborative system[4]. Phone calls, meetings or emails are necessary to establish a coordination process based on meaning negotiation through which workers attempt to make clear "what they mean by what". These communication processes between company peers (who are part of different offices or CoPs) are not formalized by the buying work-flow, and are developed according to the personal perspectives of the parts. In other words, formalized processes of knowledge exchange are constantly supported by informal and personalized meaning negotiation/coordination processes which allow people to understand each other, and to effectively achieve their goals. As shown in this example, and as depicted in our analysis, most of the knowledge exchange processes, developed within the Impresa Pizzarotti & C. S.p.A., are not able to create a unique understanding on the meaning of what is communicated. Therefore the KM system has to take into account the need expressed by organizational entities to manage knowledge with some degree of autonomy while enabling coordination processes across different KNs. As described in figure 2, a DKM system for Impresa Pizzarotti & C. S.p.A. is suggested that is composed by an enterprize knowledge repository (centralized applications) organized according to the firm's conceptual schema, and a constellation of KNs which autonomously manage local knowledge, and exchange it, through personalized processes of meaning negotiation/coordination.

According to this view, the company has recently started to accept that current knowledge exchange practices and artifacts are, as a matter of fact, characterized by a strong need of autonomy that must be sustained and compensated focusing on coordination rather than standardization. For example, in terms of artifacts, Groupware tools are being customized and used in a way that clearly mirrors how work and knowledge is actually organized within and across different KNs. In fact each yard, office and team is now able to instantiate and maintain its own local repository and work-flow processes. Organizational procedures are gradually being redesigned accordingly, allowing each yard, for example, to autonomously manage some core processes, such as purchase of specific materials, or the recruitment of specialized workers[5]. As a consequence, the EDP office and IT consultants will now focus their efforts in designing coordination/translation processes across heterogeneous nodes of content, document work-flows and categorization taxonomies rather than developing shared and standardized procedures[6].

---

[4] In the analysis it has been emerged that most of the time the buying request refers to a non standard forniture (such as a special hummer, a new mechanism, . . . ), and in the major part of this cases the purchasing office is not able to understand the real needs of requesters.

[5] For example in the Modena SCARL different views are used on a common DB, such as general notes, services, production, visits, security, quality, and so on.

[6] The EDP office is now developing two different systems in which information about

## 4    Conclusions

Through our interviews, we focused the attention on different kind of knowledge which is needed and exchanged within the firm. In particular, we proved that even if some kind of knowledge has to be centralized, organized, and managed by EDP office according to a common and shared conceptual schema, there are other types of knowledge that must be managed in an autonomous way and have to be negotiated and coordinated every time. Finally the DKM system we proposed in figure 2, seems to be more effective than other traditional and centralized systems, because it allows people to manage knowledge according to personal views, and it seems to be more consistent with how knowledge is actually managed by people. In conclusion the Impresa Pizzarotti & C S.p.A. is developing both new personalized and local procedures which allow CoPs to manage knowledge in the way they prefer; and new centralized procedures, which enable workers to contribute to the common and shared organizational knowledge.
